*Check room/day on website

Establishing a mathematical foundation for deep learning is a significant and challenging endeavor in mathematics. Recent theoretical advancements are transforming deep learning from a black box into a more transparent and understandable framework. This course offers an in-depth exploration of these developments, emphasizing a promising phenomenological approach. It is designed for those seeking an intuitive understanding of how neural networks learn from data, as well as an appreciation of their theoretical underpinnings. (...)

Session Titles:
1. Mysteries of Deep Learning
2. Frequency Principle/Spectral Bias
3. Condensation Phenomenon
4. From Condensation to Loss Landscape Analysis
5. From Condensation to Generalization Theory

Overall, this course serves as a gateway to the vibrant field of deep learning theory, inspiring participants to contribute fresh perspectives to its advancement and application.

Towards a Mathematical Foundation of Deep Learning: From Phenomena to Theory

Date

Fri. – Thu. May 2 – 8, 2025

Session Titles

1. Mysteries of Deep Learning
2. **Frequency Principle/Spectral Bias**
3. Condensation Phenomenon
4. From Condensation to Loss Landscape Analysis
5. From Condensation to Generalization

A phenomenological methodology

1. **Suspension:** Suspend the prior and belief one may hold and focus on the facts about the object.
2. **Cumulation:** Discover and cumulate all possible facts about the object. Prioritize the more informative ones.
3. **Emergence:** A new framework shall emerge once enough pieces are uncovered.

"Natural objects, for example,
must be experienced before any
theorizing about them can occur"

- Edmund Husserl

Husserl warns against this inversion of process, where theories can eclipse, misshape, or entirely ignore the vital qualities encountered in direct perception.

How to experience deep learning?

Problem: Given $\mathcal{D}:\{(x_i, y_i)\}_{i=1}^n$ and $\mathcal{H}:\{f(\cdot; \Theta) | \Theta \in \mathbb{R}^m\}$, find $f \in \mathcal{H}$ such that $f(x_i) = y_i$ for $i = 1, \dots, n$.

$$\dot{\Theta} = -\nabla_{\Theta} L(\Theta)$$

$$\Theta(0) = \Theta_0$$

$$L(\Theta) = \frac{1}{2n} \sum_{i=1}^n (f(x_i; \Theta) - y_i)^2$$

$$f_{\theta}(x) = \mathbf{W}^{[L]} \sigma \circ (\dots \mathbf{W}^{[2]} \sigma \circ (\mathbf{W}^{[1]} x + \mathbf{b}^{[1]}) + \dots) + \mathbf{b}^{[L]}$$

General observation:

$f(x_i; \Theta(\infty))$ often generalize well even when $m \gg n$.

How to experience deep learning?

Two key objects

① Trajectory in function space

$$f(\cdot, t): \mathbb{R}^+ \rightarrow \mathcal{H}$$

② Trajectory in parameter space

$$\Theta(t): \mathbb{R}^+ \rightarrow \mathbb{R}^m$$

Common strategy: choose proper statistics for observation.

Limitation: choice of statistics reflect our bias, no guarantee for effectiveness.

Can we observe the whole trajectory?

Frequency Principle

Evolution of neural network output function

$$f(x, \theta(t))$$

tanh-DNN, 200-100-100-50

Through the lens of Fourier transform $\hat{f}(\xi, \theta(t))$

Frequency Principle (F-Principle):

DNNs often fit training data from low to high frequencies during the training.

Xu, Zhang, Xiao, *Training behavior of deep neural network in frequency domain*, 2018

Nasim Rahaman et al, *On the Spectral Bias of Neural Networks*, 2018

Synthetic curve with equal amplitude

How DNN fits a 2-d image?

(a) True image

(b) DNN output

Target: image $I(\mathbf{x}) : \mathbb{R}^2 \rightarrow \mathbb{R}$

\mathbf{x} : location of a pixel

$I(\mathbf{x})$: grayscale pixel value

High-dimensional real data?

Image frequency (NOT USED)

- This frequency corresponds to the rate of change of intensity across neighboring pixels.

zero freq
Same color

high freq
Sharp edge

★ Response frequency

- Frequency of a general Input-Output mapping f .

$$\hat{f}(\mathbf{k}) = \int f(\mathbf{x}) e^{-i2\pi\mathbf{k}\cdot\mathbf{x}} d\mathbf{x}$$

$$\text{MNIST: } \mathbb{R}^{784} \rightarrow \mathbb{R}^{10}, \mathbf{k} \in \mathbb{R}^{784}$$

Goodfellow et al.

high freq: Adversarial example

Nonuniform Discrete Fourier transform (NUDFT) for training dataset $\{(\mathbf{x}_i, y_i)\}_{i=1}^n$:

$$\hat{y}_{\mathbf{k}} = \frac{1}{n} \sum_{i=1}^n y_i e^{-i2\pi \mathbf{k} \cdot \mathbf{x}_i}, \quad \hat{h}_{\mathbf{k}}(t) = \frac{1}{n} \sum_{i=1}^n h(\mathbf{x}_i, t) e^{-i2\pi \mathbf{k} \cdot \mathbf{x}_i}$$

Difficulty:

- Curse of dimensionality, i.e., $\#\mathbf{k}$ grows exponentially with dimension of problem d .

Our approaches:

- Projection, i.e., choose $\mathbf{k} = k\mathbf{p}_1$
- Filtering

Projection approach

$$\text{Relative error: } \Delta_F(k) = |\hat{h}_k - \hat{y}_k| / |\hat{y}_k|$$

MNIST

(a) Fourier domain

(b) Relative error

CIFAR10

(c) Fourier domain

(d) Relative error

Decompose frequency domain by filtering

$$\mathbf{y}_i^{\text{low},\delta} = (\mathbf{y} * G^\delta)_i$$

$$\mathbf{y}_i^{\text{high},\delta} \triangleq \mathbf{y}_i - \mathbf{y}_i^{\text{low},\delta}$$

$$e_{\text{low}} = \left(\frac{\sum_i |\mathbf{y}_i^{\text{low},\delta} - \mathbf{h}_i^{\text{low},\delta}|^2}{\sum_i |\mathbf{y}_i^{\text{low},\delta}|^2} \right)^{\frac{1}{2}}$$

$$e_{\text{high}} = \left(\frac{\sum_i |\mathbf{y}_i^{\text{high},\delta} - \mathbf{h}_i^{\text{high},\delta}|^2}{\sum_i |\mathbf{y}_i^{\text{high},\delta}|^2} \right)^{\frac{1}{2}}$$

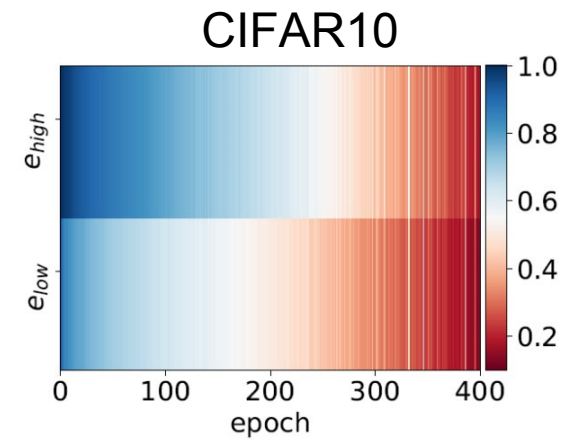

F-Principle in high-dim space

(a) $\delta = 3$, DNN

(b) $\delta = 3$, CNN

(c) $\delta = 7$, VGG

(d) $\delta = 7$, DNN

(e) $\delta = 7$, CNN

(f) $\delta = 10$, VGG

Implication of F-Principle

Xu, Zhang, Xiao, *Training behavior of deep neural network in frequency domain*, 2018

Xu, Zhang, Luo, Xiao, Ma, *Frequency Principle: Fourier Analysis Sheds Light on Deep Neural Networks*, 2019

Frequency principle for 2-d image restoration

Original Image

Epoch=20000

Epoch=50000

Epoch=1000000

F-Principle: DNNs prefer low frequencies

CIFAR10

Test accuracy: 72% %>>10%

parity

For $\vec{x} \in \{-1, 1\}^n$
 $f(\vec{x}) = \prod_{j=1}^n x_j$,
Even #'-1' $\rightarrow 1$;
Odd #'-1' $\rightarrow -1$.

Test accuracy: ~50%, random guess

Effect of early stopping

When should one stop the backpropagation and use the current parameters?

Theory of F-Principle

Theory in a idealized setting

- Consider a tanh-DNN of one-hidden layer for fitting a 1-d function f

$$h(x) = \sum_{j=1}^m a_j \sigma(w_j x + b_j),$$

$$\hat{h}(k) \approx \sum_{j=1}^m a_j \exp\left(\frac{ib_j}{w_j}\right) \exp\left(-\left|\frac{\pi k}{2w_j}\right|\right),$$

- Define the loss at frequency k

$$L(k) = \frac{1}{2} |\hat{h}(k) - \hat{f}(k)|^2$$

By Parseval's theorem: $L = \int L(k) dk = \int \frac{1}{2} |f(x) - h(x)|^2 dx$

- Compute the gradient by the loss in Fourier domain

$$\theta \leftarrow \theta - \eta \sum \frac{\partial L(k)}{\partial \theta}$$

$$\left| \frac{\partial L(k)}{\partial \theta} \right| \approx A(k) \exp\left(-\left| \frac{\pi k}{2w_i} \right| \right) G(\theta, k)$$

Where $A(k) = |\hat{h}(k) - \hat{f}(k)|$

- $A(k) > 0$:

If w_i is small, $\exp(-|\pi k/2w_i|)$ dominate, low frequencies dominate.

For $w_i \in B_\delta$, center at 0 with radius δ , if δ is small, contribution of high frequency loss is negligible.

- $A(k) \approx 0$:

small contribution from $L(k)$

Insight: **smoothness/regularity of activation function $\sigma(\cdot)$** can be converted into F-Principle through gradient-based training.

The NTK regime

$$L(\Theta) = \sum_{i=1}^n (h(x_i; \Theta) - y_i)^2$$
$$\dot{\Theta} = -\nabla_{\Theta} L(\Theta)$$

- $\partial_t h(x; \Theta) = -\sum_{i=1}^n K_{\Theta}(x, x_i) (h(x_i; \Theta) - y_i)$

Where $K_{\Theta}(x, x') = \nabla_{\Theta} h(x; \Theta) \cdot \nabla_{\Theta} h(x'; \Theta)$

- Neural Tangent Kernel (NTK) regime:

$$K_{\Theta(t)}(x, x') \approx K_{\Theta(0)}(x, x') \text{ for any } t.$$

Theorem 1. For a network of depth L at initialization, with a Lipschitz nonlinearity σ , and in the limit as the layers width $n_1, \dots, n_{L-1} \rightarrow \infty$ sequentially, the NTK $\Theta^{(L)}$ converges in probability to a deterministic limiting kernel:

$$\Theta^{(L)} \rightarrow \Theta_{\infty}^{(L)} \otimes Id_{n_L}.$$

Jacot et al., 2018

Problem simplification

$$f_{\theta}(x) = \mathbf{W}^{[L]} \sigma \circ (\dots \mathbf{W}^{[2]} \sigma \circ (\mathbf{W}^{[1]} x + \mathbf{b}^{[1]}) + \dots) + \mathbf{b}^{[L]}$$

Two-layer ReLU NN

$$h(x; \Theta) = \sum_{i=1}^n w_i \sigma(r_i(x + l_i))$$

find

$$\dot{\Theta} = -\nabla_{\Theta} L(\Theta)$$

Initialized by special Θ_0

Kernel gradient flow

$$\partial_t f(x, t) = -\sum_{i=1}^n K_{\Theta_0}(x, x_i) (f(x_i, t) - y_i)$$

Some basics of Fourier transform

Definition 1. Given a nonzero vector $\mathbf{w} \in \mathbb{R}^d$, we define the delta-like function $\delta_{\mathbf{w}} : \mathcal{S}(\mathbb{R}^d) \rightarrow \mathbb{R}$ such that for any $\phi \in \mathcal{S}(\mathbb{R}^d)$,

$$\langle \delta_{\mathbf{w}}, \phi \rangle = \int_{\mathbb{R}} \phi(y\mathbf{w}) \, dy. \quad (6)$$

Lemma 1 (Scaling property of delta-like function). Given any nonzero vector $\mathbf{w} \in \mathbb{R}^d$ with $\hat{\mathbf{w}} = \frac{\mathbf{w}}{\|\mathbf{w}\|}$, we have

$$\frac{1}{\|\mathbf{w}\|^d} \delta_{\hat{\mathbf{w}}} \left(\frac{\mathbf{x}}{\|\mathbf{w}\|} \right) = \delta_{\mathbf{w}}(\mathbf{x}). \quad (7)$$

Proof This is proved by changing of variables. In fact, for any $\phi \in \mathcal{S}(\mathbb{R}^d)$, we have

$$\begin{aligned} \left\langle \frac{1}{\|\mathbf{w}\|^d} \delta_{\hat{\mathbf{w}}} \left(\frac{\cdot}{\|\mathbf{w}\|} \right), \phi(\cdot) \right\rangle_{\mathcal{S}'(\mathbb{R}^d), \mathcal{S}(\mathbb{R}^d)} &= \langle \delta_{\hat{\mathbf{w}}}(\cdot), \phi(\|\mathbf{w}\|\cdot) \rangle_{\mathcal{S}'(\mathbb{R}^d), \mathcal{S}(\mathbb{R}^d)} \\ &= \int_{\mathbb{R}} \phi(\|\mathbf{w}\|y\hat{\mathbf{w}}) \, dy \\ &= \int_{\mathbb{R}} \phi(y\mathbf{w}) \, dy \\ &= \langle \delta_{\mathbf{w}}(\cdot), \phi(\cdot) \rangle_{\mathcal{S}'(\mathbb{R}^d), \mathcal{S}(\mathbb{R}^d)}. \end{aligned}$$

Some basics of Fourier transform

Lemma 2 (Fourier transforms of network functions). *For any unit vector $\boldsymbol{\nu} \in \mathbb{R}^d$, any nonzero vector $\boldsymbol{w} \in \mathbb{R}^d$ with $\hat{\boldsymbol{w}} = \frac{\boldsymbol{w}}{\|\boldsymbol{w}\|}$, and $g \in \mathcal{S}'(\mathbb{R})$ with $\mathcal{F}[g] \in C(\mathbb{R})$, we have, in the sense of distribution,*

$$(a) \quad \mathcal{F}_{x \rightarrow \xi}[g(\boldsymbol{\nu}^\top \boldsymbol{x})](\xi) = \delta_{\boldsymbol{\nu}}(\xi) \mathcal{F}[g](\xi^\top \boldsymbol{\nu}), \quad (8)$$

$$(b) \quad \mathcal{F}_{x \rightarrow \xi}[g(\boldsymbol{w}^\top \boldsymbol{x} + b)](\xi) = \delta_{\boldsymbol{w}}(\xi) \mathcal{F}[g] \left(\frac{\xi^\top \hat{\boldsymbol{w}}}{\|\boldsymbol{w}\|} \right) e^{2\pi i \frac{b}{\|\boldsymbol{w}\|} \xi^\top \hat{\boldsymbol{w}}}, \quad (9)$$

$$(c) \quad \mathcal{F}_{x \rightarrow \xi}[\boldsymbol{x} g(\boldsymbol{w}^\top \boldsymbol{x} + b)](\xi) = \frac{i}{2\pi} \nabla_{\xi} \left[\delta_{\boldsymbol{w}}(\xi) \mathcal{F}[g] \left(\frac{\xi^\top \hat{\boldsymbol{w}}}{\|\boldsymbol{w}\|} \right) e^{2\pi i \frac{b}{\|\boldsymbol{w}\|} \xi^\top \hat{\boldsymbol{w}}} \right]. \quad (10)$$

Linear F-Principle (LFP) dynamics

2-layer NN: $h(x; \Theta) = \sum_{i=1}^n w_i \text{ReLU}(r_i(x + l_i))$

Assumptions:

(i) NTK regime, (ii) sufficiently wide distribution of l_i .

$$\partial_t \hat{h}(\xi, t) = - \left[\frac{4\pi^2 \langle r^2 w^2 \rangle}{\xi^2} + \frac{\langle r^2 \rangle + \langle w^2 \rangle}{\xi^4} \right] (\hat{h}_p(\xi, t) - \hat{f}_p(\xi, t))$$

$\langle \cdot \rangle$: mean over all neurons at initialization

f : target function; $(\cdot)_p = (\cdot)p$, where $p(x) = \frac{1}{n} \sum_{i=1}^n \delta(x - x_i)$;

$\hat{\cdot}$: Fourier transform; ξ : frequency

aliasing

Preference induced by LFP dynamics

$$\partial_t \hat{h}(\xi, t) = - \left[\frac{4\pi^2 \langle r^2 w^2 \rangle}{\xi^2} + \frac{\langle r^2 \rangle + \langle w^2 \rangle}{\xi^4} \right] (\hat{h}_p(\xi, t) - \hat{f}_p(\xi, t))$$

low frequency
preference

$$\min_{h \in F_\gamma} \int \left[\frac{4\pi^2 \langle r^2 w^2 \rangle}{\xi^2} + \frac{\langle r^2 \rangle + \langle w^2 \rangle}{\xi^4} \right]^{-1} |\hat{h}(\xi)|^2 d\xi$$

$$\text{s.t. } h(x_i) = y_i \text{ for } i = 1, \dots, n$$

Case 1: ξ^{-2} dominant

- $\min \int \xi^2 |\hat{h}(\xi)|^2 d\xi \sim \min \int |h'(x)|^2 dx \rightarrow \text{linear spline}$

Case 2: ξ^{-4} dominant

- $\min \int \xi^4 |\hat{h}(\xi)|^2 d\xi \sim \min \int |h''(x)|^2 dx \rightarrow \text{cubic spline}$

Regularity can be changed through initialization

Case 1

$$\langle r^2 \rangle + \langle w^2 \rangle \gg 4\pi^2 \langle r^2 w^2 \rangle$$

$$\min \int \xi^2 |\hat{h}(\xi)|^2 d\xi$$

Case 2

$$4\pi^2 \langle r^2 w^2 \rangle \gg \langle r^2 \rangle + \langle w^2 \rangle$$

$$\min \int \xi^4 |\hat{h}(\xi)|^2 d\xi$$

High-dimensional Case

$$\partial_t \hat{h}(\xi, t) = - \left[\frac{\langle |r|^2 \rangle + \langle w^2 \rangle}{|\xi|^{d+3}} + \frac{4\pi^2 \langle |r|^2 w^2 \rangle}{|\xi|^{d+1}} \right] (\hat{h}_p(\xi, t) - \hat{f}_p(\xi, t))$$

where f : target function; $(\cdot)_p = (\cdot)p$, where $p(x) = \frac{1}{n} \sum_{i=1}^n \delta(x - x_i)$;

$(\hat{\cdot})$: Fourier transform; ξ : frequency.

Theorem (informal). Solution of LFP dynamics at $t \rightarrow \infty$ with initial value h_{ini} is the same as solution of the following optimization problem

$$\min_{h - h_{\text{ini}} \in F_\gamma} \int \left[\frac{\langle |r|^2 \rangle + \langle w^2 \rangle}{|\xi|^{d+3}} + \frac{4\pi^2 \langle |r|^2 w^2 \rangle}{|\xi|^{d+1}} \right]^{-1} |\hat{h}(\xi) - \hat{h}_{\text{ini}}(\xi)|^2 d\xi$$

$$\text{s.t. } h(X) = Y.$$

FP-norm and FP-space

We define the FP-norm for all function $h \in L^2(\Omega)$:

$$\|h\|_\gamma = \|\hat{h}\|_{H_\Gamma} = \left(\sum_{k \in \mathbb{Z}^{d*}} \gamma^{-2}(k) |\hat{h}(k)|^2 \right)^{1/2}$$

Next, we define the FP-space:

$$F_\gamma(\Omega) = \{h \in L^2(\Omega) : \|h\|_\gamma < \infty\}$$

A priori generalization error bound

Theorem (informal). Suppose that the real-valued target function $f \in F_\gamma(\Omega)$, h_n is the solution of the regularized model

$$\min_{h \in F_\gamma} \|h\|_\gamma \text{ s.t. } h(X) = Y$$

Then for any $\delta \in (0,1)$ with probability at least $1-\delta$ over the random training samples, the population risk has the bound

$$L(h_n) \leq \left(\|f\|_\infty + 2 \|f\|_\gamma \|\gamma\|_{l^2} \right) \left(\frac{2}{\sqrt{n}} + 4 \sqrt{\frac{2 \log(4/\delta)}{n}} \right)$$

Revisit Leo Breiman's problems (1995)

- 1. Why don't heavily parameterized neural networks overfit the data?**
2. What is the effective number of parameters?
3. Why doesn't backpropagation head for a poor local minima?
- 4. When should one stop the backpropagation and use the current parameters?**

Overparameterized DNNs still generalize well

DNNs are not black boxes--Problems

- ① How can neural networks be prevented from overfitting to noise in the training data?
- ② How can the convergence towards high-frequency components of the target function be improved during training?
- ③ Is it possible to design a model that prioritizes fitting high-frequency components before low-frequency ones during training?
- ④ What characteristics of a target function or dataset make it difficult for deep neural networks to generalize?
- ⑤ What methods or conditions can be employed to induce deep neural networks to overfit the training data, resulting in a large generalization error?

Thanks!

饮水思源 爱国荣校

Impact of initialization

Deep Neural Network

$$h(x; \theta) = h^{[H]}$$

$$h^{[j]} = \sigma(W^{[j]}h^{[j-1]} + b^{[j]})$$

$$\theta: [W^{[j]}, b^{[j]}]_{j=1, \dots, H}$$

Example: Two-layer NN

$$h_{\theta}(x) = \sum_{i=1}^{m_1} w_i^{[2]} \sigma(w_i^{[1]}x + b_i^{[1]})$$

Initialization

$$\theta(0): [W^{[j]}(0), b^{[j]}(0)]_{j=1, \dots, H}$$

$$W^{[j]}(0), b^{[j]}(0) \sim \mathcal{N}(0, \sigma_j^2)$$

$$[\sigma_j]_{j=1, \dots, H} \xrightarrow{?} h_{\theta(\infty)}(x)$$

initialization

generalization

DNN can easily overfit with bad initialization

initial

train

test

$$\sigma_j = 10$$

$$\sigma_j = 0.1$$

Impact of $f(\cdot, \Theta(0))$

Setup in the linear (NTK) regime

NNs can be linearized around initialization

$$h(\mathbf{x}, \boldsymbol{\theta}) \approx h(\mathbf{x}, \boldsymbol{\theta}_0) + \nabla_{\boldsymbol{\theta}} h(\mathbf{x}, \boldsymbol{\theta}_0) \cdot (\boldsymbol{\theta} - \boldsymbol{\theta}_0)$$

Loss

$$R_S(\boldsymbol{\theta}) = \text{dist}(\mathbf{h}(\mathbf{X}, \boldsymbol{\theta}), \mathbf{Y})$$

Neural tangent kernel (NTK)

$$k(\cdot, \cdot) = \nabla_{\boldsymbol{\theta}} h(\cdot, \boldsymbol{\theta}_0)^\top \nabla_{\boldsymbol{\theta}} h(\cdot, \boldsymbol{\theta}_0)$$

Kernel gradient flow

$$\partial_t h(\mathbf{x}, t) = -k(\mathbf{x}, \mathbf{X}) \nabla_{\mathbf{h}(\mathbf{X}, t)} \text{dist}(\mathbf{h}(\mathbf{X}, t), \mathbf{Y})$$

Equivalent optimization problems

Theorem 5 Let $\theta(t)$ be the solution of gradient flow dynamics

$$\frac{d}{dt}\theta(t) = -\nabla_{\theta}h(\mathbf{X}, \theta_0)\nabla_{h(\mathbf{X}, \theta(t))}\text{dist}(h(\mathbf{X}, \theta(t)), \mathbf{Y}) \quad (8)$$

with initial value $\theta(0) = \theta_0$, where $\nabla_{\theta}h(\mathbf{X}, \theta_0)$ is a full rank (rank n) matrix of size $m \times n$ with $m > n$. Suppose that the limit $\theta(\infty) = \lim_{t \rightarrow \infty} \theta(t)$ exists. Then $\theta(\infty)$ solves the constrained optimization problem

$$\min_{\theta} \|\theta - \theta_0\|_2, \text{ s.t.}, h(\mathbf{X}, \theta) = \mathbf{Y}. \quad (9)$$

Theorem 6 Let θ be the solution of problem (9), then $h(\mathbf{x}, \theta)$ uniquely solves the optimization problem

$$\min_{h-h_{\text{ini}} \in H_k(\Omega)} \|h - h_{\text{ini}}\|_k \quad \text{s.t.} \quad h(\mathbf{X}) = \mathbf{Y}, \quad (12)$$

In a general class, e.g., any L^p distance, choice of loss has no impact.

In practice, different loss can be considered to accelerate convergence.

Main results

Theorem 2 For a fixed kernel function $k \in C(\Omega \times \Omega)$, and training set $\{\mathbf{X}; \mathbf{Y}\}$, for any initial function $h_{\text{ini}} \in C(\Omega)$, $h_k(\cdot; h_{\text{ini}}, \mathbf{X}, \mathbf{Y})$ can be decomposed as

$$h_k(\cdot; h_{\text{ini}}, \mathbf{X}, \mathbf{Y}) = h_k(\cdot; 0, \mathbf{X}, \mathbf{Y}) + \boxed{h_{\text{ini}} - h_k(\cdot; 0, \mathbf{X}, h_{\text{ini}}(\mathbf{X}))}. \quad (6)$$

unbiased fit

bias from h_{ini}

Theorem 3 For a target function $f \in C(\Omega)$, if h_{ini} is generated from an unbiased distribution of random functions μ such that $\mathbb{E}_{h_{\text{ini}} \sim \mu} h_{\text{ini}} = 0$, then the generalization error of $h_k(\cdot; h_{\text{ini}}, \mathbf{X}, f(\mathbf{X}))$ can be decomposed as follows

$$\begin{aligned} \mathbb{E}_{h_{\text{ini}} \sim \mu} R_S(h_k(\cdot; h_{\text{ini}}, \mathbf{X}, f(\mathbf{X})), f) &= R_S(h_k(\cdot; 0, \mathbf{X}, f(\mathbf{X})), f) \\ &+ \boxed{\mathbb{E}_{h_{\text{ini}} \sim \mu} R_S(h_k(\cdot; 0, \mathbf{X}, h_{\text{ini}}(\mathbf{X})), h_{\text{ini}})}, \end{aligned}$$

where $R_S(h_k(\cdot; h_{\text{ini}}, \mathbf{X}, f(\mathbf{X})), f) = \|h_k(\cdot; h_{\text{ini}}, \mathbf{X}, f(\mathbf{X})) - f\|_{L^2(\Omega)}^2$.

**additional
generalization error**

Illustration

$$h_K(\cdot; h_{\text{ini}}, X, Y) - h_K(\cdot; 0, X, Y) = \boxed{h_{\text{ini}} - h_K(\cdot; 0, X, h_{\text{ini}}(X))}$$

bias: high freq of h_{ini}

Revisit previous experiments

AntiSymmetrical Initialization (ASI) trick

Original DNN

$$h(x, \theta) \text{ with } \theta(0) = \theta_0$$

After ASI

$$h_{\text{ASI}} = \frac{\sqrt{2}}{2} h(x, \theta) - \frac{\sqrt{2}}{2} h(x, \theta')$$
$$\theta'(0) = \theta(0) = \theta_0$$

Properties

1. $h_{\text{ASI}} = 0$ at initialization
2. $k_{\text{ASI}}(\cdot, \cdot) = k(\cdot, \cdot)$

Experiments--Boston house price dataset

Experiments—MNIST dataset
